Abstract. The Cauchy problem for the Fokker–Plank–Kolmogorov equation with a nonlocal nonlinear drift term is reduced to a similar problem for the correspondent linear equation. The relation between symmetry operators of the linear and nonlinear Fokker–Plank–Kolmogorov equations is considered. Illustrative examples of the one-dimensional symmetry operators are presented.

Key words: symmetry operators; Fokker–Plank–Kolmogorov equation; nonlinear partial differential equations

2000 Mathematics Subject Classification: 35Q58; 37J15

1 Introduction

By definition, symmetry operators leave invariant the solution set of an equation and allow to generate new solutions from the known ones (see, e.g. [1, 2]). The finding of symmetry operators is an important problem, but it rarely can be solved explicitly because the equations that determine symmetry operators are complicated and nonlinear. Therefore, special types of symmetry operators are of interest. The most affective approach is developed in the framework of the group analysis of differential equations [3, 4, 5, 6, 7] where the Lie groups of symmetry operators are considered. The Lie group generators (related to symmetries) are obtained from the determining linear equations which can be solved in a regular way when the symmetries are differential operators. The symmetries of differential equations can be considered in the context of differential geometry [5, 8, 9].

The calculation of symmetries for integro-differential equations is a more complex problem because there are no general way of choosing an appropriate structure of symmetries. The finding of symmetry operators for a nonlocal equation is usually a hopeless task. Under these circumstances, examples of symmetry operators for a nonlinear equation with nonlocal terms are of mathematical interest.

In this work we consider an approach that can be used to obtain such examples for the Fokker–Planck–Kolmogorov equation (FPKE) of special form with a quadratic nonlocal nonli-

nearity

$$\left\{ -\partial_t + \varepsilon \Delta + \partial_{\vec{x}} \left(\vec{V}(\vec{x}, t) + \varkappa \int_{\mathbb{R}^n} \vec{W}(\vec{x}, \vec{y}, t) u(\vec{y}, t) d\vec{y} \right) \right\} u(\vec{x}, t) = 0, \quad (1.1)$$

where

$$\vec{V}(\vec{x}, t) = K_1 \vec{x}, \quad \vec{W}(\vec{x}, \vec{y}, t) = K_2 \vec{x} + K_3 \vec{y}. \quad (1.2)$$

Here, $t \in \mathbb{R}^1$, $\vec{x} = (x_1, \dots, x_n)^\top \in \mathbb{R}^n$, $\vec{y} = (y_1, \dots, y_n)^\top \in \mathbb{R}^n$ are independent variables; $(x_1, \dots, x_n)^\top$ means a transpose to a vector or a matrix; $d\vec{x} = dx_1 \cdots dx_n$; the dependent variable $u(\vec{x}, t)$ is a real smooth function decreasing as $\|\vec{x}\| \rightarrow \infty$; K_1, K_2, K_3 are arbitrary constant matrices of order $n \times n$; ε and \varkappa are real parameters; $\partial_t = \partial/\partial t$; $\partial_{\vec{x}} = \partial/\partial \vec{x}$ is a gradient operator with respect to \vec{x} ; $\Delta = \partial_{\vec{x}} \partial_{\vec{x}} = \sum_{i=1}^n \partial^2/\partial x_i^2$ is a Laplace operator.

The operator of equation (1.1) is quadratic in independent variables and in derivatives and it has a nonlocal quadratic nonlinear term.

This equation serves as a simple example of a class of “near-linear” nonlocal equations [10], such that they are nonlinear but the integrability problem for them can be reduced to seeking a solution of appropriate linear equations. Nonlinear equations of such type regularly depend on the nonlinearity parameter and they possess solutions which go into solutions of the linear equation as the nonlinearity parameter tends to zero.

Equation (1.1) arises in mathematical problems and it can be used in physical applications. In particular, the FPKE (1.1), (1.2) describes the leading term of the asymptotic solutions constructed in [11] in the framework of the formalism of semiclassical asymptotics [12, 13] for equation (1.1), in which $\vec{V}(\vec{x}, t)$ and $\vec{W}(\vec{x}, t)$ are real vector functions of general form.

The semiclassical approximation is widely used in nonlinear mathematical physics, providing a possibility of constructing explicit asymptotic solutions for mathematical physics equations coefficients of which can be arbitrary smooth functions and derivatives of dependent variables are assumed small. Most of the equations solved by semiclassical methods are not exactly integrable. For these equations, semiclassical methods offer a unique opportunity to investigate them analytically.

A method of semiclassical asymptotics based on the formalism of the Maslov complex germ [12, 13, 14, 15, 16] has been developed for a many-dimensional nonstationary Hartree type equation with nonlocal nonlinearity in a class of functions localized in a neighborhood of some phase curve [17, 18, 19, 20]. This class of functions has been called the class of trajectory-concentrated functions (TCF). The Hartree type equation whose operator is quadratic in independent variables and derivatives provides another example of the class of “near-linear” nonlinear equations similar to the FPKE (1.1).

The symmetry analysis area may be augmented by the study of the symmetry features of the semiclassical approximation as the semiclassical methods are hoped to result in a new kind of symmetries for mathematical physics equations. The group properties of the semiclassical approximation were considered in quantum mechanics and in some models of the quantum field theory [21]. The semiclassical method for solving the Cauchy problem in the class of TCF’s has been developed for the Hartree type equation [17, 18, 19, 20] and for the one-dimensional FPKE [11, 22, 23]. For the Hartree type equation, symmetry operators have been found in the TCF class.

A nonlinear FPKE was used to analyze stochastic processes in various physical phenomena. In this connection, the following works where the Fokker–Plank–Kolmogorov equation with the nonlinear drift term similar to that in (1.1) was considered deserve mention (see also [10] and references therein). M. Shiino and K. Yoshida studied noise effects and phase transitions effects involving chaos-nonchaos bifurcations [24] in the framework of nonlinear Fokker–Plank

equations. These equations are shown to exhibit the property of H theorem with a Lyapunov functional that takes the form of free energy involving generalized entropies of Tsallis [25]. In [26] the stochastic resonance phenomenon is discussed; in [27] binary branching and dying processes were studied. The evolution of quantum systems was described by means of nonlinear FPKE's [28] where the nonlinearity reflects the quantum constraints imposed by the Bose and Fermi statistics.

The paper is organized as follows. In Section 2 the nonlinear FPKE is presented with necessary notations and definitions. The Cauchy problem for the nonlinear FPKE is reduced to a similar problem for the corresponding linear FPKE in the class of functions decreasing at infinity via the Cauchy problem for the first moment vector of a solution of the nonlinear FPKE. With the help of the Cauchy problem solution we construct a nonlinear evolution operator and the corresponding left inverse operator in explicit form for the nonlinear FPKE.

In Section 3 a general class of nonlinear symmetry operators is considered for the nonlinear FPKE. The symmetry operators are introduced in different ways, in particular using the evolution operator and the left inverse operator. Examples of one-dimensional symmetry operators are given in explicit form as an illustration. In Conclusion the results are discussed in the framework of symmetry analysis.

2 The Cauchy problem and the evolution operator

In our consideration, the key part is played by the Cauchy problem for the FPKE (1.1), (1.2) in the class of functions $u(\vec{x}, t)$ decreasing as $\|\vec{x}\| \rightarrow \infty$ at every point of time $t \geq 0$. To be specific, we assume that $u(\vec{x}, t)$ belongs to the Schwartz space \mathcal{S} in the variable $\vec{x} \in \mathbb{R}^n$ and regularly depends on t , i.e. $u(\vec{x}, t)$ is expanded as a power series in t about $t = 0$. Obviously, equation (1.1) can be written in the form of the balance equation

$$\partial_t u(\vec{x}, t) = \partial_{\vec{x}} \vec{B}(\vec{x}, t, u),$$

where

$$\vec{B}(\vec{x}, t, u) = \varepsilon \partial_{\vec{x}} u(\vec{x}, t) + \vec{V}(\vec{x}, t) u(\vec{x}, t) + \varkappa \int_{\mathbb{R}^n} \vec{W}(\vec{x}, \vec{y}, t) u(\vec{y}, t) d\vec{y} u(\vec{x}, t).$$

Then according to the divergence theorem, we obtain that the integral $\int_{\mathbb{R}^n} u(\vec{x}, t) d\vec{x}$ conserves in time t for every solution $u(\vec{x}, t)$ of equation (1.1). Therefore, taking the initial function $u(\vec{x}, 0) = \gamma(\vec{x})$ to be normalized, $\int_{\mathbb{R}^n} \gamma(\vec{x}) d\vec{x} = 1$, we can assume

$$\int_{\mathbb{R}^n} u(\vec{x}, t) d\vec{x} = 1, \quad t \geq 0, \quad (2.1)$$

without loss of generality. We do not pay special attention to the positive definiteness of solutions of the FPKE (1.1), leaving this requirement for specific examples (see [29] for details).

Let us write equations (1.1), (1.2) in equivalent form

$$\{-\partial_t + \hat{H}_{\text{nl}}(\vec{x}, t; \vec{X}_u(t))\} u(\vec{x}, t) = 0, \quad (2.2)$$

where the operator \hat{H}_{nl} reads

$$\hat{H}_{\text{nl}}(\vec{x}, t; \vec{X}_u(t)) = \varepsilon \Delta + \partial_{\vec{x}} (\Lambda \vec{x} + \varkappa K_3 \vec{X}_u(t)), \quad (2.3)$$

the matrix Λ is

$$\Lambda = K_1 + \varkappa K_2,$$

and the vector

$$\vec{X}_u(t) = \int_{\mathbb{R}^n} \vec{x}u(\vec{x}, t)d\vec{x} \quad (2.4)$$

is the first moment of the function $u(\vec{x}, t)$. With the obvious notation $\dot{\vec{X}}_u(t) = d\vec{X}_u(t)/dt$, we obtain immediately from (2.2)–(2.4), and (2.1)

$$\dot{\vec{X}}_u(t) = -(\Lambda + \varkappa K_3)\vec{X}_u(t). \quad (2.5)$$

Equation (2.5) can be considered the first equation of the Einstein–Ehrenfest system (EES) that describes the evolution of the moments and centered high-order moments of a solution $u(\vec{x}, t)$ of the FPKE (1.1) with the vector functions $\vec{V}(\vec{x}, t)$ and $\vec{W}(\vec{x}, t)$ of general form. The total EES for moments of all orders was derived in constructing approximate semiclassical solutions for a one-dimensional FPKE in [11].

2.1 Solution of the Cauchy problem

Let us set the Cauchy problem for equation (2.2):

$$u(\vec{x}, 0) = \gamma(\vec{x}), \quad \gamma(\vec{x}) \in \mathcal{S}, \quad \int_{\mathbb{R}^n} \gamma(\vec{x})d\vec{x} = 1. \quad (2.6)$$

Then we have the induced Cauchy problem for the vector $\vec{X}_u(t)$

$$\vec{X}_u(0) = \vec{X}_\gamma = \int_{\mathbb{R}^n} \vec{x}\gamma(\vec{x})d\vec{x} \quad (2.7)$$

determined by (2.5).

The nonlinear Cauchy problem (2.2), (2.6) is reduced to a linear one as follows. For a given initial function $\gamma(\vec{x})$ (2.6), we can seek a solution of the Cauchy problem (2.5), (2.7) independently of the solution of equation (2.2) and obtain the vector $\vec{X}_u(t)$ having the form of (2.4) due to the uniqueness of the Cauchy problem solution. Let us introduce a function $w(\vec{x}, t)$ by the equality

$$u(\vec{x}, t) = w(\vec{x} - \vec{X}_u(t), t). \quad (2.8)$$

By substitution of (2.8) in (2.2) we obtain for the function $w(\vec{x}, t)$ a linear equation:

$$-\partial_t w(\vec{x}, t) + \widehat{L}w(\vec{x}, t) = 0, \quad (2.9)$$

$$\widehat{L} = \varepsilon\Delta + \partial_{\vec{x}}\Lambda\vec{x}. \quad (2.10)$$

From (2.6) and (2.8) we have

$$w(\vec{x}, 0) = \tilde{\gamma}(\vec{x}) = \gamma(\vec{x} + \vec{X}_\gamma) \quad (2.11)$$

and

$$\int_{\mathbb{R}^n} \tilde{\gamma}(\vec{x})d\vec{x} = 1. \quad (2.12)$$

Equation (2.7) results in

$$\int_{\mathbb{R}^n} \vec{x}\tilde{\gamma}(\vec{x})d\vec{x} = 0, \quad (2.13)$$

i.e. the function $\tilde{\gamma}(\vec{x})$ is centered. Obviously, the integral $\int_{\mathbb{R}^n} w(\vec{x}, t) d\vec{x}$ conserves in time t for any solution $w(\vec{x}, t)$ of equation (2.9); then from (2.12) we have

$$\int_{\mathbb{R}^n} w(\vec{y}, t) d\vec{y} = 1.$$

Therefore, the nonlinear Cauchy problem (2.2), (2.3), (2.6) can be solved as follows. First, for a given initial function $\gamma(\vec{x})$ (2.6) we solve the linear Cauchy problem (2.9), (2.10), (2.11) with the initial function $\tilde{\gamma}(\vec{x})$ normalized by condition (2.12) and centered by (2.13). Second, we find the vector $\vec{X}_u(t)$ by solving the Cauchy problem (2.5), (2.7). Then, the solution of the nonlinear Cauchy problem (2.2), (2.3), (2.6) is given by (2.8).

Equation (2.9) is known (see, e.g., [2]) to have a solution in the form of a Gaussian wave packet:

$$w(\vec{x}, t) = \sqrt{\frac{\det Q(t)}{(2\pi\varepsilon)^n}} \exp \left[-\frac{1}{2\varepsilon} \vec{x}^\top Q(t) \vec{x} \right], \quad (2.14)$$

where $Q(t)$ is a symmetric positive-definite matrix of order $n \times n$. Substituting (2.14) in (2.9), we obtain

$$\begin{aligned} \vec{x}^\top \dot{Q}(t) \vec{x} + 2 \vec{x}^\top (Q(t))^2 \vec{x} - \vec{x}^\top \Lambda^\top Q(t) \vec{x} - \vec{x}^\top Q(t) \Lambda \vec{x} - \varepsilon \frac{d}{dt} \log \det Q(t) \\ + 2\varepsilon \text{Tr}(-Q(t) + \Lambda) = 0. \end{aligned}$$

Here $\text{Tr} \Lambda$ is the trace of the matrix Λ . Equating the coefficients of equal powers of \vec{x} , we have

$$\begin{aligned} \dot{Q}(t) + 2(Q(t))^2 - \Lambda^\top Q(t) - Q(t) \Lambda = 0, \\ -\frac{d}{dt} \log \det Q(t) + 2 \text{Tr}(-Q(t) + \Lambda) = 0. \end{aligned} \quad (2.15)$$

Let us take $Q(t)$ in the form

$$Q(t) = B(t)(C(t))^{-1}, \quad (2.16)$$

where $B(t)$ and $C(t)$ are matrices of order $n \times n$. On substitution of (2.16) in (2.15) we can write

$$\begin{aligned} \dot{B}(t) = \Lambda^\top B(t), \quad B(0) = B_0, \\ \dot{C}(t) = 2B(t) - \Lambda C(t), \quad C(0) = C_0, \end{aligned} \quad (2.17)$$

where B_0 and C_0 are arbitrary constant matrices of $n \times n$ order. We call equations (2.17) a system in variations in matrix form.

For the one-dimensional case, the linear equation (2.9) takes the form

$$\{-\partial_t + \varepsilon \partial_x^2 + \partial_x \Lambda x\} w(x, t) = 0, \quad (2.18)$$

where $\partial_x = \partial/\partial x$.

The solution (2.14) of equation (2.18) reads

$$w(x, t) = \sqrt{\frac{B(t)}{2\pi\varepsilon C(t)}} \exp \left[-\frac{B(t)}{2\varepsilon C(t)} x^2 \right],$$

where $B(t)$ and $C(t)$ are a solution of the system in variations (2.17) in the one-dimensional case. For $t = 0$ we have

$$w(x, 0) = \tilde{\gamma}(x) = \sqrt{\frac{B_0}{2\pi\varepsilon C_0}} \exp \left[-\frac{B_0}{2\varepsilon C_0} x^2 \right]. \quad (2.19)$$

Notice that the function $\tilde{\gamma}(x)$ (2.19) is normalized and centered:

$$\int_{-\infty}^{+\infty} \tilde{\gamma}(x) dx = 1, \quad \int_{-\infty}^{+\infty} x \tilde{\gamma}(x) dx = 0.$$

Then the function

$$u(x, t) = w(x - X_u(t), t) = \sqrt{\frac{B(t)}{2\pi\varepsilon C(t)}} \exp\left[-\frac{B(t)}{2\varepsilon C(t)}(x - X_u(t))^2\right] \quad (2.20)$$

will be a solution of the nonlinear equation

$$\{-\partial_t + \varepsilon\partial_x^2 + \partial_x\Lambda x + \varkappa K_3 X_u(t)\partial_x\}u(x, t) = 0, \quad (2.21)$$

with the initial condition

$$u(x, 0) = \gamma(x) = \tilde{\gamma}(x - X_\gamma) = \sqrt{\frac{B_0}{2\pi\varepsilon C_0}} \exp\left[-\frac{B_0}{2\varepsilon C_0}(x - X_\gamma)^2\right]. \quad (2.22)$$

The vector $X_u(t) = \int_{-\infty}^{+\infty} xu(x, t)dx$ in equation (2.21) satisfies the condition

$$\dot{X}_u(t) = -(\Lambda + \varkappa K_3)X_u(t), \quad X_u(0) = X_\gamma. \quad (2.23)$$

2.2 The evolution operator for a nonlinear FPKE

Let us rewrite the solution of the above nonlinear Cauchy problem in terms of the corresponding nonlinear evolution operator.

Let $G_{\text{lin}}(t, s, \vec{x}, \vec{y})$ be the Green function of the linear equation (2.9), i.e.

$$w(\vec{x}, t) = \int_{\mathbb{R}^n} G_{\text{lin}}(t, s, \vec{x}, \vec{y}) \tilde{\gamma}(\vec{y}) d\vec{y}.$$

Substituting \vec{x} for $\vec{x} - \vec{X}_u(t)$, we find

$$w(\vec{x} - \vec{X}_u(t), t) = \int_{\mathbb{R}^n} G_{\text{lin}}(t, s, \vec{x} - \vec{X}_u(t), \vec{y}) \gamma(\vec{y} + \vec{X}_\gamma) d\vec{y}.$$

According to (2.8) and (2.11), the function

$$u(\vec{x}, t) = \int_{\mathbb{R}^n} G_{\text{nl}}(t, s, \vec{x}, \vec{y}, \gamma) \gamma(\vec{y}) d\vec{y} = \int_{\mathbb{R}^n} G_{\text{lin}}(t, s, \vec{x} - \vec{X}_u(t), \vec{y} - \vec{X}_\gamma) \gamma(\vec{y}) d\vec{y} \quad (2.24)$$

is a solution of the nonlinear equation (2.2), (2.3) with the initial condition (2.6). Therefore,

$$G_{\text{nl}}(t, s, \vec{x}, \vec{y}, \gamma) = G_{\text{lin}}(t, s, \vec{x} - \vec{X}_u(t), \vec{y} - \vec{X}_\gamma) \quad (2.25)$$

is the kernel of the evolution operator for the nonlinear equation (2.2). Here $\gamma(\vec{x}) = u(\vec{x}, s)$ and the initial time $t = 0$ is replaced by $t = s$.

Suppose that a solution of the system in variations (2.17) has the form

$$B(t) = M_1(t, s)B_0, \quad C(t) = M_2(t, s)B_0 + M_3(t, s)C_0, \quad (2.26)$$

where $M_1(t, s)$, $M_2(t, s)$, and $M_3(t, s)$ are the matrix blocks of order $n \times n$ of the matriciant (evolution matrix) of the system in variations (2.17). These matrix blocks must satisfy the condition

$$\dot{M} = AM, \quad M(s) = \mathbb{I}_{2n \times 2n}, \quad (2.27)$$

where

$$M = M(t, s) = \begin{pmatrix} M_1(t, s) & 0 \\ M_2(t, s) & M_3(t, s) \end{pmatrix}, \quad A = \begin{pmatrix} \Lambda^\top & 0 \\ 2\mathbb{I}_{n \times n} & -\Lambda \end{pmatrix}.$$

Set the Cauchy problem for (2.26):

$$B(s) = B_0^\top = B_0, \quad C(s) = C_0 = 0.$$

The Green's function of equation (2.9) is known and can be taken as (see, e.g., [2]):

$$G_{\text{lin}}(t, s, \vec{x}, \vec{y}) = \frac{1}{\sqrt{(2\pi\varepsilon)^n \det [M_2(t, s)(M_1(t, s))^{-1}]}} \times \exp \left\{ -\frac{1}{2\varepsilon} (\vec{x} - M_3(t, s)\vec{y})^\top [M_1(t, s)(M_2(t, s))^{-1}] (\vec{x} - M_3(t, s)\vec{y}) \right\}.$$

Then the nonlinear evolution $\widehat{U}(t, s, \cdot)$ operator (2.24) reads

$$\widehat{U}(t, s, \gamma)(\vec{x}) = \int_{\mathbb{R}^n} G_{\text{nl}}(t, s, \vec{x}, \vec{y}, \gamma) \gamma(\vec{y}) d\vec{y}. \quad (2.28)$$

The left-inverse operator $\widehat{U}^{-1}(t, s, \cdot)$ for the operator (2.28) is

$$\widehat{U}^{-1}(t, s, u)(\vec{x}) = \int_{\mathbb{R}^n} G_{\text{nl}}^{-1}(t, s, \vec{x}, \vec{y}, u) u(\vec{x}, t) d\vec{x}. \quad (2.29)$$

Here $G_{\text{nl}}^{-1}(t, s, \vec{x}, \vec{y}, u)$ is the kernel of the left-inverse operator, which is obtained from (2.25) if we substitute t for s and s for t . The explicit form of this function is

$$G_{\text{nl}}^{-1}(t, s, \vec{x}, \vec{y}, u) = \frac{1}{\sqrt{(2\pi\varepsilon)^n \det [M_2(s, t)(M_1(s, t))^{-1}]}} \times \exp \left\{ -\frac{1}{2\varepsilon} (\vec{x} - \vec{X}_\gamma - M_3(s, t)(\vec{y} - \vec{X}_u(t)))^\top [M_1(s, t)(M_2(s, t))^{-1}] \times (\vec{x} - \vec{X}_\gamma - M_3(s, t)(\vec{y} - \vec{X}_u(t))) \right\}.$$

The Green's function for the one-dimensional equation (2.18) is

$$G_{\text{lin}}(t, s, x, y) = \sqrt{\frac{M_1(t, s)}{2\pi\varepsilon M_2(t, s)}} \exp \left[-\frac{1}{2\varepsilon} \frac{M_1(t, s)}{M_2(t, s)} (x - M_3(t, s)y)^2 \right],$$

where $M_1(t, s)$, $M_2(t, s)$, $M_3(t, s)$ are solution of the system in variation (2.27) in the one-dimensional case.

The kernel of the evolution operator for the nonlinear equation (2.21) takes the form

$$G_{\text{nl}}(t, s, x, y, \gamma) = G_{\text{lin}}(t, s, x - X_u(t), y - X_\gamma) \quad (2.30) \\ = \sqrt{\frac{M_1(t, s)}{2\pi\varepsilon M_2(t, s)}} \exp \left[-\frac{1}{2\varepsilon} \frac{M_1(t, s)}{M_2(t, s)} (x - X_u(t) - M_3(t, s)(y - X_\gamma))^2 \right],$$

where $X_u(t)$ satisfies equation (2.23). The evolution operator (2.28) with the kernel (2.30) is written as

$$u(x, t) = \widehat{U}(t, s, \gamma)(x) = \int_{-\infty}^{+\infty} G_{\text{lin}}(t, s, x - X_u(t), y - X_\gamma) \gamma(y) dy. \quad (2.31)$$

Here the function $u(x, t)$ having the form of (2.31) is a solution of equation (2.21).

Notice that direct calculation of the action of the evolution operator (2.28) on the function $\gamma(y)$ having the form of (2.22) gives the function (2.20):

$$\begin{aligned}\widehat{U}(t, s, \gamma)(\vec{x}) &= \int_{-\infty}^{+\infty} \sqrt{\frac{M_1(t, s)}{2\pi\varepsilon M_2(t, s)}} \\ &\times \exp \left[-\frac{1}{2\varepsilon} \frac{M_1(t, s)}{M_2(t, s)} (x - X_u(t) - M_3(t, s)(y - X_\gamma))^2 \right] \\ &\times \sqrt{\frac{B_0}{2\pi\varepsilon C_0}} \exp \left[-\frac{B_0}{2\varepsilon C_0} (y - X_\gamma)^2 \right] dy \\ &= \sqrt{\frac{B(t)}{2\pi\varepsilon C(t)}} \exp \left[-\frac{B(t)}{2\varepsilon C(t)} (x - X_u(t))^2 \right].\end{aligned}$$

Conversely, the action of the left-inverse operator (2.29) on the function (2.20) in the one-dimensional case gives the function (2.22):

$$\begin{aligned}\widehat{U}^{-1}(t, s, u)(\vec{x}) &= \int_{-\infty}^{+\infty} \sqrt{\frac{M_1(s, t)}{2\pi\varepsilon M_2(s, t)}} \\ &\times \exp \left[-\frac{1}{2\varepsilon} \frac{M_1(s, t)}{M_2(s, t)} (x - X_\gamma - M_3(s, t)(y - X_u(t)))^2 \right] \\ &\times \sqrt{\frac{B(t)}{2\pi\varepsilon C(t)}} \exp \left[-\frac{B(t)}{2\varepsilon C(t)} (y - X_u(t))^2 \right] dy \\ &= \sqrt{\frac{B_0}{2\pi\varepsilon C_0}} \exp \left[-\frac{B_0}{2\varepsilon C_0} (x - X_\gamma)^2 \right].\end{aligned}$$

Because the solution of the nonlinear equation (2.2) is reduced to seeking the solution of linear equation (2.9) in terms of the moment $\vec{X}_u(t)$ (2.5), the symmetry operators of these two equations are closely connected.

Equation (2.9) with the operator \widehat{L} having the form of (2.10) is a special case of the linear evolution equation quadratic in derivatives $\partial_{\vec{x}}$ and independent variables \vec{x} . This equation is known to be integrated in explicit form (see, e.g., [2]) which in turn leads to integrability of the nonlinear FPKE (2.2), (2.3) according to (2.8) or (2.24). The basis of solutions and the Green's function for equation (2.9) can be constructed with the help of symmetry operators of special form following, for example, [2, 30, 31].

Consider the symmetry operators for (2.9) and (2.2).

3 The symmetry operators

The symmetry operators for equation (1.1) can be found in various ways following the general ideas of symmetry analysis [2, 3, 4, 5, 6].

3.1 The determining equation and intertwining

Let us construct for a function $\gamma(\vec{x})$ of the space \mathcal{S} the function $u(\vec{x}, t)$ of (2.8) using the solutions of the Cauchy problems (2.5), (2.7) for the vector $\vec{X}_u(t)$ and (2.9), (2.11) for $w(\vec{x}, t)$.

Let us take an operator $\widehat{a}(\vec{x})$ acting in the space \mathcal{S} as the initial operator for a time depending operator $\widehat{A}(\vec{x}, t)$:

$$\widehat{A}(\vec{x}, 0) = \widehat{a}(\vec{x}).$$

The function

$$\gamma_A(\vec{x}) = \frac{1}{\alpha_A} \widehat{a}(\vec{x}) \gamma(\vec{x}), \quad \alpha_A = \int_{\mathbb{R}^n} \widehat{a}(\vec{x}) \gamma(\vec{x}) d\vec{x}. \quad (3.1)$$

determines the vector \vec{X}_{γ_A} by formula (2.7), where $\gamma(\vec{x})$ is replaced by $\gamma_A(\vec{x})$. Taking the vector \vec{X}_{γ_A} as the initial condition for equation (2.5), we find the vector $\vec{X}_{u_A}(t)$.

Obviously, the operator $\widehat{A}(\vec{x}, t)$ determined by the conditions

$$(-\partial_t + \widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_{u_A}(t))) \widehat{A}(\vec{x}, t) = \widehat{B}(\vec{x}, t) (-\partial_t + \widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_u(t))), \quad (3.2)$$

$$\widehat{A}(\vec{x}, 0) = \widehat{a}(\vec{x}) \quad (3.3)$$

is a symmetry operator for equation (2.2). Here $\widehat{B}(\vec{x}, t)$ is an operator such that $\widehat{B}(\vec{x}, t)(0) = 0$. This operator plays the part of a Lagrangian multiplier and it is determined together with $\widehat{A}(\vec{x}, t)$.

Equation (3.2) is the determining equation for the symmetry operators of equation (2.2). In general, (3.2) is a nonlinear operator equation. But, given the initial function $\gamma(\vec{x})$ and the initial operator $\widehat{a}(\vec{x})$, we can find the vectors $\vec{X}_u(t)$ and $\vec{X}_{u_A}(t)$ without solving the equation (2.2). On substitution of these vectors in (3.2) the operators $\widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_u(t))$ and $\widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_{u_A}(t))$ become linear. Then we can assume that $\widehat{a}(\vec{x})$, $\widehat{A}(\vec{x}, t)$, and $\widehat{B}(\vec{x}, t)$ are linear operators in (3.2).

Notice that in the general case the operators \widehat{A} and \widehat{B} depend on $\vec{X}_u(t)$, $\vec{X}_{u_A}(t)$, i.e.

$$\widehat{A} = \widehat{A}(\vec{x}, t; \vec{X}_u(t), \vec{X}_{u_A}(t)), \quad \widehat{B} = \widehat{B}(\vec{x}, t; \vec{X}_u(t), \vec{X}_{u_A}(t)).$$

If $\widehat{B}(\vec{x}, t) = \widehat{A}(\vec{x}, t)$ then $\widehat{A}(\vec{x}, t)$ is called the *intertwining* operator for the linear operators, satisfying the condition

$$(-\partial_t + \widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_{u_A}(t))) \widehat{A}(\vec{x}, t) = \widehat{A}(\vec{x}, t) (-\partial_t + \widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_u(t))), \quad (3.4)$$

$$\widehat{A}(\vec{x}, 0) = \widehat{a}(\vec{x}). \quad (3.5)$$

If the operator $\widehat{a}(\vec{x})$ is given in (3.2), (3.3) (or in (3.4), (3.5)), these conditions are the Cauchy problems determining the operator $\widehat{A}(\vec{x}, t)$.

Now, let $u(\vec{x}, t)$ be a solution of the Cauchy problem (2.2), (2.3), (2.6), and the operator \widehat{A} is determined by the solution of the Cauchy problem (3.2), (3.3) or (3.4), (3.5). Then we immediately obtain that the function

$$u_A(\vec{x}, t) = \widehat{A}(\vec{x}, t; \vec{X}_u(t), \vec{X}_{u_A}(t)) u(\vec{x}, t) \quad (3.6)$$

is a solution of the Cauchy problem

$$\partial_t u_A(\vec{x}, t) = \widehat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_{u_A}(t)) u_A(\vec{x}, t),$$

$$u_A(\vec{x}, 0) = \gamma_A(\vec{x}) = \frac{1}{\alpha_A} \widehat{a}(\vec{x}) \gamma(\vec{x}).$$

Therefore, the operator $\widehat{A}(\vec{x}, t; \vec{X}_u(t), \vec{X}_{u_A}(t))$ is a symmetry operator of the nonlinear FPKE (2.2), (2.3).

Notice that the operator $\widehat{A}(\vec{x}, t; \vec{X}_u(t), \vec{X}_{u_A}(t))$ in (3.6) is nonlinear due to the presence of the vectors $\vec{X}_u(t)$, and $\vec{X}_{u_A}(t)$.

3.2 Symmetry operators of nonlinear and linear FPKE

We now deduce a relation connecting two solutions of the nonlinear FPKE (2.2), (2.3) using a symmetry operator of the linear equation (2.9), (2.10). This relation can be considered a symmetry operator for the nonlinear FPKE.

To this end consider equation (2.8) which connects the nonlinear Cauchy problem (2.6) with the linear Cauchy problem (2.11).

Let $\widehat{A}(\vec{x}, t)$ be a symmetry operator of the linear equation (2.9). Then the function

$$w_A(\vec{x}, t) = \frac{1}{\widetilde{\alpha}_A} \widehat{A}(\vec{x}, t) w(\vec{x}, t), \quad \widetilde{\alpha}_A = \int_{\mathbb{R}^n} \widehat{A}(\vec{x}, 0) w(\vec{x}, 0) d\vec{x},$$

is another solution of the linear equation, which is determined by (2.9), (2.10). For $t = 0$ we have

$$w_A(\vec{x}, 0) = \frac{1}{\widetilde{\alpha}_A} \widehat{A}(\vec{x}, 0) \tilde{\gamma}(\vec{x}) \equiv \gamma_A(\vec{x})$$

and

$$\int_{\mathbb{R}^n} \gamma_A(\vec{x}) d\vec{x} = 1$$

which leads to normalization of the function $w_A(\vec{x}, t)$:

$$\int_{\mathbb{R}^n} w_A(\vec{x}, t) d\vec{x} = 1.$$

On the other hand, the function $w_A(\vec{x}, t)$ is not centered for a symmetry operator $\widehat{A}(\vec{x}, t)$ of general form. In other words, for $t = 0$ the vector

$$\vec{\lambda}_A = \int_{\mathbb{R}^n} \vec{x} w_A(\vec{x}, 0) d\vec{x} = \int_{\mathbb{R}^n} \vec{x} \gamma_A(\vec{x}) d\vec{x}$$

is nonzero.

To construct a solution of the nonlinear equation (2.2), which would correspond to the solution $w_A(\vec{x}, t)$ of the linear equation (2.9) with the use of relation (2.8), the function $w_A(\vec{x}, t)$, being a solution of equation (2.9), should be centered.

We can immediately check that equation (2.9) is invariant under the change of variables $t' = t$, $\vec{x}' = \vec{x} - \vec{l}(t)$, where $\vec{l}(t)$ satisfies the condition $\dot{\vec{l}}(t) = -\Lambda \vec{l}(t)$.

Taking into account this property, let us introduce a vector

$$\vec{l}_A(t) = \int_{\mathbb{R}^n} \vec{x} w_A(\vec{x}, t) d\vec{x}$$

which satisfies the Cauchy problem

$$\dot{\vec{l}}_A(t) = -\Lambda \vec{l}_A(t), \quad \vec{l}_A(0) = \vec{\lambda}_A.$$

Then the function

$$\tilde{w}_A(\vec{x}, t) = w_A(\vec{x} + \vec{l}_A(t), t)$$

satisfies equation (2.9) and the initial condition

$$\tilde{w}_A(\vec{x}, 0) = w_A(\vec{x} + \vec{\lambda}_A, 0) = \gamma_A(\vec{x} + \vec{\lambda}_A).$$

The function $\gamma_A(\vec{x} + \vec{\lambda}_A)$ is normalized and centered. The same is true for $\tilde{w}_A(\vec{x}, t)$.

Following (2.8), we now construct a solution $v_A(\vec{x}, t)$ of the nonlinear FPKE (2.2) related to $\tilde{w}_A(\vec{x}, t)$. Consider a vector $\vec{Y}(t)$ such that

$$\dot{\vec{Y}}(t) = -(\Lambda + \varkappa K_3)\vec{Y}(t), \quad \vec{Y}(0) = \vec{\lambda}_A.$$

Immediate check shows that the function

$$v_A(\vec{x}, t) = \tilde{w}_A(\vec{x} - \vec{Y}(t), t)$$

satisfies the equation

$$\begin{aligned} \{ -\partial_t + \varepsilon\Delta + \partial_{\vec{x}}(\Lambda\vec{x} + \varkappa K_3\vec{Y}(t)) \} v_A(\vec{x}, t) &= 0, \\ v_A(\vec{x}, 0) &= \tilde{w}_A(\vec{x} - \vec{\lambda}_A, 0) = \gamma_A(\vec{x}). \end{aligned}$$

Notice that

$$\begin{aligned} \vec{X}_{v_A}(t) &= \int_{\mathbb{R}^n} v_A(\vec{x}, t) \vec{x} d\vec{x}, \quad \vec{X}_{v_A}(0) = \int_{\mathbb{R}^n} \vec{x} \gamma_A(\vec{x}) d\vec{x} = \vec{\lambda}_A, \\ \dot{\vec{X}}_{v_A}(t) &= -(\Lambda + \varkappa K_3)\vec{X}_{v_A}(t), \end{aligned}$$

then

$$\vec{Y}(t) = \vec{X}_{v_A}(t).$$

Therefore, $v_A(\vec{x}, t)$ satisfies the nonlinear FPKE (2.2). The relation between the solutions $u(\vec{x}, t)$ and $v_A(\vec{x}, t)$ reads

$$\begin{aligned} v_A(\vec{x}, t) &= \tilde{w}_A(\vec{x} - \vec{Y}(t), t) = w_A(\vec{x} - \vec{Y}(t) + \vec{l}_A(t), t) \\ &= \frac{1}{\tilde{\alpha}_A} \hat{A}(\vec{x} - \vec{Y}(t) + \vec{l}_A(t), t) w(\vec{x} - \vec{Y}(t) + \vec{l}_A(t), t) \\ &= \frac{1}{\tilde{\alpha}_A} \hat{A}(\vec{x} - \vec{Y}(t) + \vec{l}_A(t), t) u(\vec{x} - \vec{Y}(t) + \vec{l}_A(t) + \vec{X}_u(t), t). \end{aligned}$$

This equation determines a symmetry operator \hat{A}_{nl} of the nonlinear FPKE (2.2):

$$\begin{aligned} u_A(\vec{x}, t) &= v_A(\vec{x}, t) \equiv \hat{A}_{\text{nl}}(\vec{x}, t) u(\vec{x}, t) \\ &= \frac{1}{\alpha_A} \hat{A}(\vec{x} - \vec{Y}(t) + \vec{l}_A(t), t) u(\vec{x} - \vec{Y}(t) + \vec{l}_A(t) + \vec{X}_u(t), t). \end{aligned} \quad (3.7)$$

3.3 Symmetry operators in terms of an operator Cauchy problem

Let us reformulate the construction of symmetry operators for the nonlinear FPKE (2.2), (2.3) in terms of an operator Cauchy problem.

Consider the nonlinear Cauchy problem (2.2), (2.6) associated with the Cauchy problem (2.5), (2.7) for the vector $\vec{X}_u(t)$ having the form of (2.4).

With an operator

$$\hat{a}(\vec{x}) : \mathcal{S} \rightarrow \mathcal{S} \quad (3.8)$$

acting on the initial function $\gamma(\vec{x}) \in \mathcal{S}$ of the Cauchy problem (2.6), we define a function $\gamma_A(\vec{x})$ of the form (3.1), which is taken as an initial condition for the Cauchy problem for a function $u_A(\vec{x}, t)$

$$\{ -\partial_t + \hat{H}_{\text{nl}}(\vec{x}, t, \vec{X}_{u_A}(t)) \} u_A(\vec{x}, t) = 0,$$

$$u_A(\vec{x}, 0) = \gamma_A(\vec{x}),$$

where the vector $\vec{X}_{u_A}(t)$ is determined by the conditions

$$\begin{aligned} \dot{\vec{X}}_{u_A}(t) &= -(\Lambda + \varkappa K_3)\vec{X}_{u_A}(t), \\ \vec{X}_{u_A}(0) &= \vec{X}_{\gamma_A}, \quad \vec{X}_{\gamma_A} = \int_{\mathbb{R}^n} \vec{x} \gamma_A(\vec{x}) d\vec{x}. \end{aligned}$$

Notice that given the function $\gamma(\vec{x})$ and the operator $\hat{a}(\vec{x})$, we can find $\vec{X}_{u_A}(t)$ not finding a solution of the FPKE (2.2).

We can immediately verify that the two functions

$$w(\vec{x}, t) = u(\vec{x} + \vec{X}_u(t), t), \tag{3.9}$$

$$w_A(\vec{x}, t) = u_A(\vec{x} + \vec{X}_{u_A}(t), t) \tag{3.10}$$

are solutions of the linear equation (2.9) and the initial conditions are

$$w(\vec{x}, 0) = \gamma(\vec{x} + \vec{X}_\gamma), \quad w_A(\vec{x}, 0) = \gamma_A(\vec{x} + \vec{X}_{\gamma_A}).$$

Define a linear operator $\widehat{A}(\vec{x}, t)$ by an operator equation

$$[-\partial_t + \widehat{L}(\vec{x}, t), \widehat{A}(\vec{x}, t)] = 0$$

with the initial condition

$$\widehat{A}(\vec{x}, 0) = \widehat{a}(\vec{x}),$$

where $L(\vec{x}, t)$ is defined in (2.10). It can be shown that

$$\widehat{A}(\vec{x}, t)w(\vec{x}, t) = \widehat{A}(\vec{x} + \vec{l}_A(t), t)w(\vec{x} + \vec{l}_A(t), t).$$

Due to the uniqueness of the Cauchy problem solution, we have

$$w_A(\vec{x}, t) = \widehat{A}(\vec{x}, t)w(\vec{x}, t).$$

In view of (3.9), (3.10) we have

$$u_A(\vec{x} + \vec{X}_{u_A}(t), t) = \widehat{A}(\vec{x}, t)u(\vec{x} + \vec{X}_u(t), t)$$

or

$$u_A(\vec{x}, t) = \widehat{A}(\vec{x} - \vec{X}_{u_A}(t), t)u(\vec{x} - \vec{X}_{u_A}(t) + \vec{X}_u(t), t). \tag{3.11}$$

This relation defines a symmetry operator $\widehat{A}_{\text{nl}}(\vec{x}, t)$ of the nonlinear FPKE (2.2):

$$u_A(\vec{x}, t) = \widehat{A}_{\text{nl}}(\vec{x}, t)u(\vec{x}, t).$$

3.4 Symmetry operators in terms of an evolution operator

Using the evolution operator (2.28) and left-inverse operator (2.29), we can obtain symmetry operators for the nonlinear FPKE (2.2).

Let $\widehat{a}(\vec{x})$ be an operator (3.8) acting on an initial function $\gamma(\vec{x})$, and $u(\vec{x}, t)$ is the solution of the Cauchy problem (2.2), (2.6). Then the function

$$u_A(\vec{x}, t) = \widehat{U}(t, s, \widehat{a}\widehat{U}^{-1}(t, s, u))(\vec{x}) \quad (3.12)$$

is a solution of the nonlinear FPKE corresponding the initial function $\gamma_A(\vec{x})$ of the form (3.1). Equation (3.12) defines a symmetry operator \widehat{A}_{nl} for the nonlinear FPKE (2.2):

$$u_A(\vec{x}, t) = \widehat{A}_{\text{nl}}(\vec{x}, t)u(\vec{x}, t). \quad (3.13)$$

The one-dimensional case of (3.12) reads

$$u_A(x, t) = \widehat{A}_{\text{nl}}(x, t)u(x, t) = \widehat{U}(t, s, \widehat{a}\widehat{U}^{-1}(t, s, u))(x), \quad (3.14)$$

where $\widehat{U}(t, s, \cdot)$ and $\widehat{U}^{-1}(t, s, \cdot)$ are determined by (2.28) and (2.29) in the one-dimensional case.

Consider an operator $\widehat{a}(x, t)$ of the form

$$\begin{aligned} \widehat{a}(x, t) &= M_1(t, s)(x - X_u(t)) + (\varepsilon M_2(t, s) + M_3(t, s))\partial_x, \\ \widehat{a}(x, s) &= x - X_\gamma + \partial_x, \quad X_\gamma = X_u(s). \end{aligned}$$

Here $M_1(t, s)$, $M_2(t, s)$, and $M_3(t, s)$ are solutions of the system in variations (2.27) in the one-dimensional case. Then for (3.14) we have

$$\begin{aligned} u_A(x, t) &= \lim_{\tau \rightarrow t} \widehat{U}(t, s, [\partial_z + z - X_\gamma]\widehat{U}^{-1}(\tau, s, u))(x) \\ &= \lim_{\tau \rightarrow t} \int_{-\infty}^{+\infty} dy \int_{-\infty}^{+\infty} dz G_{\text{nl}}(t, s, x, z, \gamma_A) [\partial_z + z - X_\gamma] G_{\text{nl}}^{-1}(\tau, s, z, y, u) u(y, \tau) \\ &= \int_{-\infty}^{+\infty} dy \int_{-\infty}^{+\infty} dz \lim_{\tau \rightarrow t} \frac{1}{2\pi\varepsilon} \sqrt{\frac{M_1(t, s)M_1(s, \tau)}{M_2(t, s)M_2(s, \tau)}} \\ &\quad \times \exp \left\{ -\frac{1}{2\varepsilon} \left(x - X_{u_A}(t) - M_3(t, s)(z - X_{\gamma_A}) \right)^2 \frac{M_1(t, s)}{M_2(t, s)} \right\} [\partial_z + z - X_\gamma] \\ &\quad \times \exp \left\{ -\frac{1}{2\varepsilon} \left(z - X_\gamma - M_3(s, \tau)(y - X_u(\tau)) \right)^2 \frac{M_1(s, \tau)}{M_2(s, \tau)} \right\} u(y, \tau) \\ &= [M_1(t, s)(x - X_{u_A}(t)) + M_3(t, s)X_{\gamma_A} - X_\gamma + (\varepsilon M_2(t, s) + M_3(t, s))\partial_x] \\ &\quad \times u(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t) \\ &= \widehat{a}(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t) u(x + X_u(t) - X_{u_A}(t) \\ &\quad + M_3(t, s)(X_{\gamma_A} - X_\gamma), t). \end{aligned}$$

Therefore, we have

$$\begin{aligned} u_A(x, t) &= \widehat{A}_{\text{nl}}(x, t)u(x, t) = \widehat{a}(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t) \\ &\quad \times u(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t). \end{aligned} \quad (3.15)$$

In calculating the symmetry operators we have used the following relations:

$$M_1(t, s)M_1(s, \tau) = M_1(t, \tau), \quad M_2(t, \tau) = M_1(s, \tau)M_2(t, s) + M_2(s, \tau)M_3(t, s),$$

which follow from (2.27) in the one-dimensional case.

Equality (3.15) determines a symmetry operator in explicit form for equation (2.21). This symmetry operator generates solutions of equation (2.21). Let us illustrate this by an example.

By acting with the operator (3.15) on the function (2.20), we obtain

$$\begin{aligned} u_A(x, t) &= \widehat{a}(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t) \times \\ &\quad \times u(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t) \\ &= \frac{1}{C(t)} \left(C_0 - \frac{1}{\varepsilon} B_0 \right) (x - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma)) \\ &\quad \times u(x + X_u(t) - X_{u_A}(t) + M_3(t, s)(X_{\gamma_A} - X_\gamma), t). \end{aligned} \quad (3.16)$$

The function $u_A(x, t)$ (3.16) is a solution of the equation

$$\{-\partial_t + \varepsilon \partial_x^2 + \partial_x \Lambda x + \varkappa K_3 X_{u_A}(t) \partial_x\} u_A(x, t) = 0.$$

Notice that the symmetry operators determined by (3.13) are consistent with the operators (3.7) and (3.11) in the one-dimensional case. Moreover, the operator determined by (3.15) corresponds the operator determined by relation (3.7)

$$\widehat{A}_{\text{nl}}(\vec{x}, t) = \widehat{A}_{\text{nl}}(\vec{x} + \vec{X}_u(t), t),$$

which follows from $\dot{M}_3(t, s)(X_{\gamma_A} - X_\gamma) = -\Lambda M_3(t, s)(X_{\gamma_A} - X_\gamma)$.

4 Conclusion

Symmetry analysis of an equation is usually performed when solutions of the equation are not known, and the basic purpose consists in finding as wide as possible classes of partial solutions by using the symmetries of the equation.

It should be noted that a direct calculation of symmetry operators for a nonlinear equation is, as a rule, difficult because of the complexity of the determining equations [32]. The basic subject for study is the symmetries related to the generators of one-parameter subgroups of a Lie group of symmetry operators [3]. The determining equations for the symmetries are linear, and to solve them, it is necessary to set the structure of the symmetries. Finding of nonlocal symmetries for differential equations or differential symmetries for nonlocal equations from the determining equations, faces mathematical problems.

In this context, the algorithm proposed in this work to calculate the symmetry operators for the FPKE in explicit form is of interest as it provides a possibility to consider the properties of symmetry operators for a nontrivial nonlinear equation. The algorithm is stated in terms of a direct nonlinear evolution operator and the corresponding left-inverse operator, which enables one to vary the structure of the obtained symmetry operators.

As for the considered equation the evolution operator is found, the symmetry operators are not of interest for finding of partial solutions of the equation. However, the symmetry operators can be used to study the properties of the solutions obtained. Furthermore the algebra of symmetry operators of the linear FPKE (2.9) (see, e.g. [33]) can be used to study the symmetry operators of the nonlinear equation (2.2).

The developed approach permits a generalization for FPKE's with a smooth operator symbol of arbitrary form. In this case, we deal with a solution of the FPKE approximate in the small parameter ε [21]. The FPKE considered in this work arises in constructing the leading term of semiclassical asymptotics for a FPKE with arbitrary coefficients.
